Rhythmic entrainment source separation:

Optimizing analyses of neural responses to rhythmic sensory stimulation

Michael X Cohen, Rasa Gulbinaite

**Fig. S1.** This figure shows how simulated and real SSVEPs contain non-stationarities that are represented by the side-lobes of the sensory flicker frequency. Panel A shows an example of time-varying amplitudes in a simulated 7 Hz SSVEP that produce non-zero power outside 7 Hz. This is the motivation for using wider filters to reconstruct the time-course of SSVEP-related activity. Panel B shows an example of real EEG data during a 17 Hz visual flicker. The data contain non-stationarities in amplitude and in frequency. These non-stationarities are often the focus of analyses in cognitive neuroscience investigations; the RESS procedure preserves these nonstationarities.
